QMathParser is a small, easy-to-use math expression parser (evaluator) that has been developed in C++. It is small (in terms of code size, not library size), and not difficult to use. Simplifying complex math expressions: To start, you can avoid the use of libraries such as GMP, MPFR, and MPC, to perform many math calculations. QMathParser will perform basic math operations (such as additions, multiplications, and divisions) on complex math expressions. Additionally, you can use QMathParser to evaluate expressions that include advanced operators (such as the Pythagorean theorem, the hyperbolic functions, and complex values). Its native C++ library is much faster than those libraries. Evaluating math expressions: QMathParser includes a command-line program that allows you to evaluate math expressions. Usage: qMathParser examples: QMathParser makes it easy to perform complex calculations with mathematical expressions. It may be useful for you to know that the designers and maintainers of QMathParser use the Open Source toolkit code (in their style) to build the software. This means that they themselves test that the software does what they say it does. You are thus using a tool which checks for errors and warnings, and which includes tools that check the code for security vulnerabilities. Furthermore, this code is thoroughly reviewed before release, and supported by an active community of users and developers. The user interface is very simple, with just one main control. The use of the other controls is explained in the manual, so please read it carefully. QMathParser is free for you to use and/or distribute. If you have any comments or suggestions, contact me using the contact information at the bottom of the page. I am also always pleased to hear from

users.In September 2010 the High Court declared that the "red tailed phyllostomid bat" (Glossophaga soricina) should have the status of a species: it was the first insect bat in the world to be accorded this status. If you want to know more about the bat then you can read the evidence and High Court judgment here. During the many years of the court case, we have been submitting evidence. Some of this is really useful and can help you with conservation projects. Let's look at it quickly. The bat is small with a wing span

QMathParser is a small, easy to use math expression parser (evaluator) developed in C++ that uses the fast muParser library. QMathParser is able to perform basic math operations, as well as calculations that include advanced operators and functions. QMathParser started out as a text-based calculator in December 2004. During the first month, the program worked only on numbers with no decimals, and did not support many of the built-in functions and operators (like sqrt, log, ln, exp, cos, sin, tan, etc). Then in January 2005, QMathParser was converted to a graphical user interface, and began to feature a number of the advanced features that are included in other math expression tools. In December 2005, QMathParser was updated to version 2.0.0, in which a lot of new features were added, including support for the trigonometric functions sin(), cos(), tan(), and asin() and a set of non-standard operators. The update also included a major overhaul of the GUI and the underlying code. In February 2006, QMathParser was updated to version 2.1.0, in which the code was rewritten from scratch. The changed included extensive testing and bug fixes. In March 2006,

QMathParser received a major update to version 2.2.0, in which all text-based expression parsing code was deleted (no more text-based parsing). All parsing was then done in a graphical user interface, giving QMathParser a much faster evaluator, with most of the parsing done when the input expression is changed. In January 2007, QMathParser received an update to version 2.3.0, in which the user interface was updated to Qt4. What is new in this release: Changed the build system and the build process. Fixed bugs and added new examples. Added a new calculator for the easy creation of custom functions. Added a new example of a constant function. Added a workaround for QImage::load() and prevented program crash. Added a "Remember my choice" option to the Evaluate() function. Added new font sizes for the GUI and for the documentation. Added a new example to the online demo. Added a workaround for automatic seeding of random number generators. Added a new feature: initialization of QMathParser with a batch of sample expressions. Added 09e8f5149f

This is a small math expression evaluator written in C++. The goal of QMathParser is to provide an easy to use, fast and well documented math expression parser that can evaluate math expressions and expressions in other programming languages. QMathParser has a small code base. It is written entirely in C++ and therefore is easy to understand and use. It is tiny and fast. All features are described in the help menu. QMathParser has an easy to use interface. Only one window is needed to use it. It provides a simple menu and buttons that perform the desired operation. New features are implemented with a button click. QMathParser does not require additional libraries. It will work with both Python 2.x and Python 3.0. Features: ```c++ - Option to load a Python math expression to process. - Option to load a math expressions from a file. - All operators, non-operator characters, and operators are optimized to be searched quickly and minimized. - All operators, non-operator characters, and operators are tokenized and offered as a list of tuples. - Option to evaluate an expression with choice of deterministic or non-deterministic algorithms. - Basic math operations. Sum, product, division, subtraction, multiply, exponentiation, logarithmic and trigonometric functions. - Option to rewrite the expression into a more condensed form. - Option to check if the expression is syntactically correct. - Option to define custom functions that can be used in math expressions. - Option to show a representation of the evaluated expression. - Option to generate a readable representation of the expression. - Option to export the expression in LaTeX. - Option to export the expression as a MathML document. - Option to change the expression into a matrix. - Option to select a variable or an operator

for substitution. - Option to check if the expression is valid or not. - Option to perform operations with existing functions in Python. - Option to save the expression in a file. - Option to automatically save the expression. - Option to change the color of the math expression. - Option to invert the color of the expression. - Option to color the selected characters. - Option to apply styles to the selected characters. - Option to perform a search for math expressions or math expressions in a file. - Option to display the matches found in a

**What's New In QMathParser?**

QMathParser is a parser for the muParser math expression library. It allows you to create math expressions and evaluate them. Supported Functions: + = plus - = minus * = multiply / = divide ^ = power % = modulo = = assignment ( +=, -=, *=, /=, %= ) ( ) = group ( ) [ ] = group ( ) [ ] () : optional argument and = logical and (equality) or = logical or (inclusion) not = not conditional integer (integer) (integer) = integer (integer) = integer (integer) (integer) ( ) integer ( ) integer ( ) integer ( ) ( ) floating point number ( ) floating point number ( ) floating point number ( ) ( ) floating point number ( ) floating point number ( ) floating point number ( ) ( ) floating point number ( ) floating point number ( ) floating point number ( ) floating point number ( ) ( ) floating point number ( ) floating point number ( ) floating point number ( ) floating point number ( ) floating point number ( ) ( ) floating point number ( ) floating point number ( ) floating point number ( ) ( ) floating point number ( ) floating point number ( ) floating point number ( ) ( ) floating point number ( ) floating point number ( ) Install: sudo apt-get install libmuParser-dev Run: ./configure make sudo make install Required Libraries: libmuParser-dev libmuParser (necessary for compiling)

Additional information: 1. Written in C++ (only supporting C++11). 2. Full source code is available on 3. There are no unit tests. 4. Example Code available here: What is "Evaluate" and "Help"? QMathParser has two actions, "Evaluate" and "Help". Evaluate is used to evaluate a math expression, which returns the result of evaluation. Evaluate is only accessible from the main menu and the help window. Help is used to display the functions/operators and their help text. Help is accessible from both main menu and the help window. Help is especially useful for learning the language because it shows its description

**System Requirements:**

Minimum: OS: Windows 7/8/8.1 Processor: Intel Core2 Duo 1.6 GHz or better Memory: 1 GB RAM Graphics: 1024 MB DirectX: Version 9.0 Network: Broadband Internet connection Storage: 600 MB available space Additional Notes: • Internet Explorer 10 or newer is required to play the game • Keyboard and Mouse are required to play • Check out for all the legal stuff
